Mazda recommends SAE 80w90. Also Redline makes good quality stuff. I recommend MT90. We run it in all our racecars. All rights reserved Back to top. Hardly anyone ever changes the transmission fluid, and really, can you blame them. For all the engineering that was put into the RX7, Mazda made a major mistake with the transmission. The fill plug is on the side of the case, tucked between the transmission itself and the body of the car. Very inconvenient to get to, and completely impossible to access with a jug of fluid or pitcher. And before you ask, no, you cannot just pour the fluid through the shifter opening. It is a completely separate assembly from the transmission. While it is very efficient, it is also quite expensive and beyond the realm of the driveway mechanic. Not to mention that a lift is required as the pump does not fit under the car. Many people have tried some interesting solutions, from long tubes, to turkey basters, to beer funnels. Each one works to a degree, but usually more transmission fluid ends up on the driveway than in the car. This annoyance has caused me to develop the solution below. Using air pressure from a shop compressor, or 12V compressor, it will put 2.5 quarts into the transmission in under 5 minutes, with not a drop spilled. Use the jacks to lift the car and set it on jack stands. The jack stands should be positioned under heavy frame members such as engine cross members, the rear differential brace or the differential itself. Do not use regular jacks to support the car while you are under it as doing so is just an invitation to be crushed. <https://www.coverdolls.com/userfiles/camion-komatsu-830e-manual.xml>

Car ramps can also be used but can be more awkward to set up, especially if you are lacking floor jack. I personally prefer ramps because they just look more stable than stands. Either way, you want the car level and high enough so you can fit underneath. This ensures that they are not rusted in place, and you can actually put fluid in after you take it out. I personally use a set of ViceGrips to break them loose often with the aid of a hammer and then a monkey wrench to finish the job. The nonturbo transmissions have one fill plug, while the turbo models have two. This is shown below pictures stolen shamelessly from the Haynes repair manual. As I recall, the plug for nonturbo cars is 24MM, but I simply use a pair of vice grips. For turbo cars, open it the same way you would the fill plug described above. Carefully remove the plug and allow the fluid to drain out. While the fluid is draining, clean all the metal shavings from the magnetic plug a small amount of shavings is normal, huge mounds are excessive and indicate a problem such as worn bearings and move onto the next step. Simply remove the cap from your jug of fluid and drill a hole through the middle. Make the hole one size smaller than the plastic tube. Now, smear some fluid on the tube and slide it through the hole until there is enough tube to reach the bottom of the jug. You should end up with an assembly like the one shown below. It should be above the fluid level to avoid spillage. If possible, try not to get any plastic shavings into the fluid. Then simply screw the cap back onto the jug. It should look like the picture below I prefer to wrap a few turns of Teflon tape around the threads, then tighten snugly. The tape helps seal the plug with less torque on the threads. This makes it much easier to remove next time. Put the open end of the plastic tube into the fill hole on the side of the

transmission. <http://eatlahgroup.com/attachment/camera-user-manuals.xml>

You should be able to catch the end on the internals of the transmission to prevent it from falling out. Attach your ball inflator or toy inflator again, the inflatable toy adapter is best to your air source and turn on the air. I usually use a small 12V compressor, connected to the battery with jumper cables. Now, with the air nozzle slightly moistened with transmission fluid, push it through the hole in the jug to form a decent seal. Watch in amazement as fluid begins to flow through the plastic tube and into the transmission. Personally, I try to never get it past 25 PSI. If you go too far, the jug will burst, completely covering everything around you with transmission fluid. Ask me how I know. It is helpful to use the varying pressure of your fingers to control the air leakage around the nozzle, thus controlling the pressure in the jug. It sounds a lot more complicated than it really is. When the jug is empty, simply refill with fluid and continue until the transmission is full. Clean off the treads of the fill plug and wrap with a few turns of Teflon tape. Install the plug in the transmission and tighten snugly with a monkey wrench. Now, safely lower the car. This can actually blow out the seals at the worst, and will coat the underside of your car with transmission fluid at the least. A small 180 degree bend at the transmission end of the tube forms a hook that will keep the tube firmly in the transmission. If it explodes, it will make a horrible mess and may actually be dangerous. Also, the input shaft's spline section on the 198795 turbo transmission is larger than its nonturbo counterparts. These transmissions were offered during this time first as 4speed units and later as 5speed units. While the basic gear assembly was strong, the synchro rings were somewhat fragile. These transmission cases were both lighter and stronger than that of the previous generation.

The smooth gear case was integrated with the bell housing, making removal of the bell housing impossible. It is not uncommon to find this assembly retrofitted into earlier RX7 chassis, utilizing our 225mm race clutch discs either 4 or 6 puck with a turbo spline hub. The primary cause is lack of adequate oil around the bushing to cool the housing. As a result, the extension housing will expand from the heat, the bushing may spin in its bore, the rear seal will pop out, and then the transmission oil will leak out. Manual Transmission Ratios Synchro life varied drastically, depending on the skill and technique of the driver, but generally ended up in the 20,000 to 40,000 mile range. Second gear was the usual problem, but all the others could readily fail as well. Such failures, which result in grinding the synchro teeth when shifting, were frequently brought on by just one missed shift. Therefore, full clutch release and smooth lever movement are essential. The damage to internal parts increases rapidly with continual use. The three slots cut in the rings to engage the synchro keys weaken the rings so much that any unusual force causes them to bend at the slots, and once they distort, replacement is the only answer. When replacing transmission parts, be sure to use the correct parts for your particular year, model, and chassis number. This lapping is accomplished by rotating the ring against the gear with fine valvelapping compound in between for 20 to 30 seconds. The results are immediate and impressive. Next, inspect the throwout bearing for roughness in the bearing push in on the bearing when checking it. If there is any doubt as to its condition, replace it with a Mazda stock part. This problem can usually be identified by deep grooves worn in the pressure plate diaphragm spring fingers. Wipe a bit of heavy grease into the recess inside the throwout bearing so that it will slide easily on its guide.

In our experience, when a transmission is removed, the input shaft tends to hang up temporarily on the eccentric shaft. This distorts the front transmission seal slightly and can cause leakage. While the same replacement recommendation applies to the rear transmission seal this item can be replaced with the transmission in place with a minimum of trouble. Vivid Racing is now introducing Nagisa Auto new Transmission Oil Pan made out of high quality cast aluminum transmission oil pan. It is lightweight and durable. Heat exchange fins and larger capacity keep gear oil temperature low. At higher temperatures, the transmission gear oil can lose its efficiency, and cause notchy shifting, a

common cause of the 2nd to 5th gear misshift which will damage the synchromesh gears. The significantly larger heat exchange fins and increased capacity on this piece help dissipate heat much quicker. Capacity is increased by .5 liters. We can contact you via phone or email.
